WO 2004/043963 A1

PYRROLOBENZODIAZEPINES

The present invention relates to pyrrolobenzodiazepines (PBDs), and in particular pyrrolobenzodiazepines having a C2-C3 double bond, an aryl group at the C2 position, and particular substituents on that C2 aryl group.

Background to the invention

Some pyrrolobenzodiazepines (PBDs) have the ability to recognise and bond to specific sequences of DNA; the preferred sequence is PuGpu. The first PBD antitumour antibiotic, anthramycin, was discovered in 1965 (Leimgruber, et al., *J. Am. Chem. Soc.*, **87**, 5793-5795 (1965); Leimgruber, et al., *J. Am. Chem. Soc.*, **87**, 5791-5793 (1965)). Since then, a number of naturally occurring PBDs have been reported, and over 10 synthetic routes have been developed to a variety of analogues (Thurston, et al., *Chem. Rev.* **1994**, 433-465 (1994)). Family members include abbeymycin (Hochlowski, et al., *J. Antibiotics*, **40**, 145-148 (1987)), chicamycin (Konishi, et al., *J. Antibiotics*, **37**, 200-206 (1984)), DC-81 (Japanese Patent 58-180 487; Thurston, et al., *Chem. Brit.*, **26**, 767-772 (1990); Bose, et al., *Tetrahedron*, **48**, 751-758 (1992)), mazethramycin (Kuminoto, et al., *J. Antibiotics*, **33**, 665-667 (1980)), neothramycins A and B (Takeuchi, et al., *J. Antibiotics*, **29**, 93-96 (1976)), porothramycin (Tsunakawa, et al., *J. Antibiotics*, **41**, 1366-1373 (1988)), prothracarcin (Shimizu, et al., *J. Antibiotics*, **29**, 2492-2503 (1982); Langley and Thurston, *J. Org. Chem.*, **52**, 91-97 (1987)), sibanomicin (DC-102) (Hara, et al., *J. Antibiotics*, **41**, 702-704 (1988); Itoh, et al., *J. Antibiotics*, **41**, 1281-1284 (1988)), sibiromycin (Leber, et al., *J. Am. Chem. Soc.*, **110**, 2992-2993 (1988)) and tomamycin (Arima, et al., *J. Antibiotics*, **25**, 437-444 (1972)). PBDs are of the general structure:

2

They differ in the number, type and position of substituents, in both their aromatic A rings and pyrrolo C rings, and in the degree of saturation of the C ring. In the B-ring there is

5 either an imine (N=C), a carbinolamine (NH-CH(OH)), or a carbinolamine methyl ether (NH-CH(OMe)) at the N10-C11 position which is the electrophilic centre responsible for alkylating DNA. All of the known natural products have an (S)-configuration at the chiral C11a position which provides them with a right-handed 10 twist when viewed from the C ring towards the A ring. This gives them the appropriate three-dimensional shape for isohelicity with the minor groove of B-form DNA, leading to a snug fit at the binding site (Kohn, In *Antibiotics III*. Springer-Verlag, New York, pp. 3-11 (1975); Hurley and Needham-VanDevanter, *Acc. Chem. Res.*, 19, 230-237 (1986)). Their ability to form an adduct in 15 the minor groove, enables them to interfere with DNA processing, hence their use as antitumour agents.

The present inventors have previously disclosed, in WO 00/12508,

20 that the following compounds, amongst many other, are cytotoxic:

More recently, in Cooper. N., et al., *Chem. Commun.*, 16, 1764-

1765 (2002), the following compound was also disclosed as being

25 cytotoxic alongside the compounds shown above.

Disclosure of the invention

The present inventors have now discovered that a certain class of 5 these compounds exhibit surprising activity against cancer cell lines, compared to the known compounds discussed above.

Therefore, a first aspect of the present invention is a compound of formula (I):

10

Alkylene

5 C_{3-12} alkylene: The term " C_{3-12} alkylene", as used herein, pertains to a bidentate moiety obtained by removing two hydrogen atoms, either both from the same carbon atom, or one from each of two different carbon atoms, of a hydrocarbon compound having from 3 to 12 carbon atoms (unless otherwise specified), which may be 10 aliphatic or alicyclic, and which may be saturated, partially unsaturated, or fully unsaturated. Thus, the term "alkylene" includes the sub-classes alkenylene, alkynylene, cycloalkylene, etc., discussed below.

15 Examples of linear saturated C_{3-12} alkylene groups include, but are not limited to, $-(\text{CH}_2)_n-$ where n is an integer from 3 to 12, for example, $-\text{CH}_2\text{CH}_2\text{CH}_2-$ (propylene), $-\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2-$ (butylene), $-\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2-$ (pentylene) and $-\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2-$ (heptylene).

Unless otherwise specified, included in the above are the well known ionic, salt, solvate, and protected forms of these substituents. For example, a reference to carboxylic acid (-COOH) also includes the anionic (carboxylate) form (-COO⁻), a

15 salt or solvate thereof, as well as conventional protected forms.

Similarly, a reference to an amino group includes the protonated form (-N⁺HR¹R²), a salt or solvate of the amino group, for example, a hydrochloride salt, as well as conventional protected forms of an amino group. Similarly, a reference to a hydroxyl

20 group also includes the anionic form (-O⁻), a salt or solvate thereof, as well as conventional protected forms.

Isomers, Salts, Solvates, Protected Forms, and Prodrugs

Certain compounds may exist in one or more particular geometric,

25 optical, enantiomeric, diastereomeric, epimeric, atropic, stereoisomeric, tautomeric, conformational, or anomeric forms, including but not limited to, cis- and trans-forms; E- and Z-forms; c-, t-, and r- forms; endo- and exo-forms; R-, S-, and meso-forms; D- and L-forms; d- and l-forms; (+) and (-) forms; 30 keto-, enol-, and enolate-forms; syn- and anti-forms; synclinal- and anticinal-forms; α - and β -forms; axial and equatorial forms; boat-, chair-, twist-, envelope-, and halfchair-forms; and combinations thereof, hereinafter collectively referred to as "isomers" (or "isomeric forms").

35

Note that, except as discussed below for tautomeric forms, specifically excluded from the term "isomers", as used herein,

are structural (or constitutional) isomers (i.e. isomers which differ in the connections between atoms rather than merely by the position of atoms in space). For example, a reference to a methoxy group, $-\text{OCH}_3$, is not to be construed as a reference to its structural isomer, a hydroxymethyl group, $-\text{CH}_2\text{OH}$. Similarly, a reference to ortho-chlorophenyl is not to be construed as a reference to its structural isomer, meta-chlorophenyl. However, a reference to a class of structures may well include structurally isomeric forms falling within that class (e.g. C₁₋₇ alkyl includes n-propyl and iso-propyl; butyl includes n-, iso-, sec-, and tert-butyl; methoxyphenyl includes ortho-, meta-, and para-methoxyphenyl).

The above exclusion does not pertain to tautomeric forms, for example, keto-, enol-, and enolate-forms, as in, for example, the following tautomeric pairs: keto/enol (illustrated below), imine/enamine, amide/imino alcohol, amidine/amidine, nitroso/oxime, thioketone/enethiol, N-nitroso/hydroxyazo, and nitro/aci-nitro.

20

Note that specifically included in the term "isomer" are compounds with one or more isotopic substitutions. For example, H may be in any isotopic form, including ^1H , ^2H (D), and ^3H (T); C 25 may be in any isotopic form, including ^{12}C , ^{13}C , and ^{14}C ; O may be in any isotopic form, including ^{16}O and ^{18}O ; and the like.

Unless otherwise specified, a reference to a particular compound includes all such isomeric forms, including (wholly or partially) 30 racemic and other mixtures thereof. Methods for the preparation (e.g. asymmetric synthesis) and separation (e.g. fractional crystallisation and chromatographic means) of such isomeric forms are either known in the art or are readily obtained by adapting the methods taught herein, or known methods, in a known manner.

Unless otherwise specified, a reference to a particular compound also includes ionic, salt, solvate, and protected forms of thereof, for example, as discussed below.

5 It may be convenient or desirable to prepare, purify, and/or handle a corresponding salt of the active compound, for example, a pharmaceutically-acceptable salt. Examples of pharmaceutically acceptable salts are discussed in Berge, et al., *J. Pharm. Sci.*, **66**, 1-19 (1977).

10

For example, if the compound is anionic, or has a functional group which may be anionic (e.g. -COOH may be -COO⁻), then a salt may be formed with a suitable cation. Examples of suitable inorganic cations include, but are not limited to, alkali metal ions such as Na⁺ and K⁺, alkaline earth cations such as Ca²⁺ and Mg²⁺, and other cations such as Al³⁺. Examples of suitable organic cations include, but are not limited to, ammonium ion (i.e. NH₄⁺) and substituted ammonium ions (e.g. NH₃R⁺, NH₂R₂⁺, NHR₃⁺, NR₄⁺). Examples of some suitable substituted ammonium ions are those derived from: ethylamine, diethylamine, dicyclohexylamine, triethylamine, butylamine, ethylenediamine, ethanolamine, diethanolamine, piperazine, benzylamine, phenylbenzylamine, choline, meglumine, and tromethamine, as well as amino acids, such as lysine and arginine. An example of a common quaternary ammonium ion is N(CH₃)₄⁺.

If the compound is cationic, or has a functional group which may be cationic (e.g. -NH₂ may be -NH₃⁺), then a salt may be formed with a suitable anion. Examples of suitable inorganic anions include, but are not limited to, those derived from the following inorganic acids: hydrochloric, hydrobromic, hydroiodic, sulfuric, sulfurous, nitric, nitrous, phosphoric, and phosphorous.

Examples of suitable organic anions include, but are not limited to, those derived from the following organic acids: 2-acetyoxybenzoic, acetic, ascorbic, aspartic, benzoic, camphorsulfonic, cinnamic, citric, edetic, ethanesulfonic,

It may be convenient or desirable to prepare, purify, and/or handle a corresponding solvate of the active compound. The term "solvate" is used herein in the conventional sense to refer to a 15 complex of solute (e.g. active compound, salt of active compound) and solvent. If the solvent is water, the solvate may be conveniently referred to as a hydrate, for example, a mono-hydrate, a di-hydrate, a tri-hydrate, etc.

20 Solvates of particular relevance to the present invention are those where the solvent adds across the imine bond of the PBD moiety, which is illustrated below where the solvent is water or an alcohol ($R^A\text{OH}$, where R^A is an ether substituent as described above):

These forms can be called the carbinolamine and carbinolamine ether forms of the PBD. The balance of these equilibria depend on the conditions in which the compounds are found, as well as the nature of the moiety itself.

30

In general any nucleophilic solvent is capable of forming such solvates as illustrated above for hydroxylic solvents. Other nucleophilic solvents include thiols and amines.

It may be convenient or desirable to prepare, purify, and/or handle the active compound in a chemically protected form. The term "chemically protected form" is used herein in the conventional chemical sense and pertains to a compound in which one or more reactive functional groups are protected from undesirable chemical reactions under specified conditions (e.g. pH, temperature, radiation, solvent, and the like). In practice, well known chemical methods are employed to reversibly render unreactive a functional group, which otherwise would be reactive, under specified conditions. In a chemically protected form, one or more reactive functional groups are in the form of a protected or protecting group (also known as a masked or masking group or a blocked or blocking group). By protecting a reactive functional group, reactions involving other unprotected reactive functional groups can be performed, without affecting the protected group; the protecting group may be removed, usually in a subsequent step, without substantially affecting the remainder of the molecule. See, for example, "Protective Groups in Organic Synthesis" (Green, T. and Wuts, P.; 3rd Edition; John Wiley and Sons, 1999).

A wide variety of such "protecting", "blocking", or "masking" methods are widely used and well known in organic synthesis. For example, a compound which has two nonequivalent reactive functional groups, both of which would be reactive under specified conditions, may be derivatized to render one of the functional groups "protected", and therefore unreactive, under the specified conditions; so protected, the compound may be used as a reactant which has effectively only one reactive functional group. After the desired reaction (involving the other functional group) is complete, the protected group may be "deprotected" to return it to its original functionality.

For example, a hydroxy group may be protected as an ether (-OR) or an ester (-OC(=O)R), for example, as: a t-butyl ether; a benzyl, benzhydryl (diphenylmethyl), or trityl (triphenylmethyl)

ether; a trimethylsilyl or t-butyldimethylsilyl ether; or an acetyl ester ($-\text{OC}(=\text{O})\text{CH}_3$, $-\text{OAc}$).

For example, an aldehyde or ketone group may be protected as an 5 acetal ($\text{R}-\text{CH}(\text{OR})_2$) or ketal ($\text{R}_2\text{C}(\text{OR})_2$), respectively, in which the carbonyl group ($>\text{C=O}$) is converted to a diether ($>\text{C}(\text{OR})_2$), by reaction with, for example, a primary alcohol. The aldehyde or ketone group is readily regenerated by hydrolysis using a large excess of water in the presence of acid.

10

For example, an amine group may be protected, for example, as an amide ($-\text{NRCO-R}$) or a urethane ($-\text{NRCO-OR}$), for example, as: a methyl amide ($-\text{NHCO-CH}_3$); a benzyloxy amide ($-\text{NHCO-OCH}_2\text{C}_6\text{H}_5$, $-\text{NH-Cbz}$); as a t-butoxy amide ($-\text{NHCO-OC}(\text{CH}_3)_3$, $-\text{NH-Boc}$); a 2-biphenyl-15 2-propoxy amide ($-\text{NHCO-OC}(\text{CH}_3)_2\text{C}_6\text{H}_4\text{C}_6\text{H}_5$, $-\text{NH-Bpoc}$), as a 9-fluorenylmethoxy amide ($-\text{NH-Fmoc}$), as a 6-nitroveratryloxy amide ($-\text{NH-Nvoc}$), as a 2-trimethylsilylethoxy amide ($-\text{NH-Teoc}$), as a 2,2,2-trichloroethoxy amide ($-\text{NH-Troc}$), as an allyloxy amide ($-\text{NH-Alloc}$), as a 2(-phenylsulphonyl)ethoxy amide ($-\text{NH-Psec}$); 20 or, in suitable cases (e.g., cyclic amines), as a nitroxide radical ($>\text{N-O}^\cdot$).

For example, a carboxylic acid group may be protected as an ester for example, as: an C_{1-7} alkyl ester (e.g. a methyl ester; a t-butyl ester); a C_{1-7} haloalkyl ester (e.g. a C_{1-7} trihaloalkyl ester); a tri C_{1-7} alkylsilyl- C_{1-7} alkyl ester; or a C_{5-20} aryl- C_{1-7} alkyl ester (e.g. a benzyl ester; a nitrobenzyl ester); or as an amide, for example, as a methyl amide.

30 For example, a thiol group may be protected as a thioether ($-\text{SR}$), for example, as: a benzyl thioether; an acetamidomethyl ether ($-\text{S-CH}_2\text{NHC}(=\text{O})\text{CH}_3$).

It may be convenient or desirable to prepare, purify, and/or 35 handle the active compound in the form of a prodrug. The term "prodrug", as used herein, pertains to a compound which, when metabolised (e.g. *in vivo*), yields the desired active compound.

Typically, the prodrug is inactive, or less active than the active compound, but may provide advantageous handling, administration, or metabolic properties.

5 For example, some prodrugs are esters of the active compound (e.g. a physiologically acceptable metabolically labile ester). During metabolism, the ester group (-C(=O)OR) is cleaved to yield the active drug. Such esters may be formed by esterification, for example, of any of the carboxylic acid groups (-C(=O)OH) in 10 the parent compound, with, where appropriate, prior protection of any other reactive groups present in the parent compound, followed by deprotection if required.

15 Also, some prodrugs are activated enzymatically to yield the active compound, or a compound which, upon further chemical reaction, yields the active compound (for example, as in ADEPT, GDEPT, LIDEPPT, etc.). For example, the prodrug may be a sugar derivative or other glycoside conjugate, or may be an amino acid ester derivative.

20 In particular, prodrugs of pyrrolobenzodiazepines are described in WO 00/12507, which is incorporated herein by reference. In these prodrugs a nitrogen protecting group which can be removed *in vivo* (e.g. enzymatically, using light) is bound to the 25 nitrogen of the imine group, with the carbon of the imine group bearing a hydroxy, ester or thioester group. Examples of this form of protection include:

30 , which is nitroreductase labile (e.g. using ADEPT/GDEPT);

which is glutathione labile (e.g. using NPEPT).

General synthetic routes

A key intermediate in the synthesis of the compounds of the present invention is the following compound, an enol triflate, of formula (A) :

10

wherein the groups R⁶ to R⁹ are as for the final product, SEM represents a trimethyl silyl ethoxy methyl group, and OTf represents the group OSO₂CF₃. The synthesis of this compound is described in detail in WO 00/12508, which is incorporated herein by reference. In particular, reference is made to scheme 7 on page 24, where the above compound is designated as intermediate P. The SEM protecting group can be replaced by other suitable nitrogen protecting groups.

20 The route from this compound to the desired final product is illustrated in scheme 1.

Scheme 1

The key enol triflate intermediate (A) can be converted to the 5 appropriate SEM protected dilactam (B) by use of a Suzuki coupling reaction, i.e. palladium catalysed cross coupling of the enol triflate (A) with the appropriate arylboron derivative.

The SEM protected dilactam (B) can then be converted to the 10 desired final compound of formula (I) by reduction, which leads to a protected carbinolamine intermediate, which can then be treated to remove the SEM protecting group. The reduction of the dilactam (B) can be accomplished by, for example, sodium 15 tetraborohydride, whilst a suitable means for removing the SEM protecting group is treatment with silica gel.

This synthesis route is equally applicable to the synthesis of dimers.

20 Further Uses

The present invention also provides compounds as described in the first aspect of the invention which regulate (e.g. inhibit) cell proliferation. Thus, the present invention also provides methods of regulating (e.g. inhibiting) cell proliferation, *in vitro* or 25 *in vivo*, comprising contacting a cell with an effective amount of a compound of the first aspect of the invention.

In particular, this inhibition may be of certain cell lines as disclosed in the examples.

One of ordinary skill in the art is readily able to determine whether or not a candidate compound regulate (e.g. inhibit) cell proliferation. For example, assays which may conveniently be used to assess the activity offered by a particular compound are described in the examples below.

10 For example, a sample of cells (e.g. from a tumour) may be grown *in vitro* and a test compound brought into contact with said cells, and the effect of the compound on those cells observed. As an example of "effect" the morphological status of the cells (e.g. alive or dead, etc.) may be determined. Where the test 15 compound is found to exert an influence on the cells, this may be used as a prognostic or diagnostic marker of the efficacy of the compound in methods of treating a patient carrying cells of the same cellular type.

20 Methods of Treatment

As described above, the second aspect of the invention provide the use of a compound of the first aspect of the invention in a method of therapy. Also provided is a method of treatment, comprising administering to a subject in need of treatment a 25 therapeutically-effective amount of a compound of the first aspect of the invention, preferably in the form of a pharmaceutical composition, which is the third aspect of the present invention. The term "therapeutically effective amount" is an amount sufficient to show benefit to a patient. Such 30 benefit may be at least amelioration of at least one symptom. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of what is being treated. Prescription of treatment, e.g. decisions on dosage, is within the responsibility of general practitioners and 35 other medical doctors.

A compound may be administered alone or in combination with other treatments, either simultaneously or sequentially dependent upon the condition to be treated. Examples of treatments and therapies include, but are not limited to, chemotherapy (the 5 administration of active agents, including, e.g. drugs; surgery; and radiation therapy.

Pharmaceutical compositions according to the present invention, and for use in accordance with the present invention, may 10 comprise, in addition to the active ingredient, i.e. a compound of formula I, a pharmaceutically acceptable excipient, carrier, buffer, stabiliser or other materials well known to those skilled in the art. Such materials should be non-toxic and should not interfere with the efficacy of the active ingredient. The 15 precise nature of the carrier or other material will depend on the route of administration, which may be oral, or by injection, e.g. cutaneous, subcutaneous, or intravenous.

Pharmaceutical compositions for oral administration may be in 20 tablet, capsule, powder or liquid form. A tablet may comprise a solid carrier or an adjuvant. Liquid pharmaceutical compositions generally comprise a liquid carrier such as water, petroleum, animal or vegetable oils, mineral oil or synthetic oil. Physiological saline solution, dextrose or other saccharide 25 solution or glycols such as ethylene glycol, propylene glycol or polyethylene glycol may be included. A capsule may comprise a solid carrier such a gelatin.

For intravenous, cutaneous or subcutaneous injection, or 30 injection at the site of affliction, the active ingredient will be in the form of a parenterally acceptable aqueous solution which is pyrogen-free and has suitable pH, isotonicity and stability. Those of relevant skill in the art are well able to prepare suitable solutions using, for example, isotonic vehicles 35 such as Sodium Chloride Injection, Ringer's Injection, Lactated Ringer's Injection. Preservatives, stabilisers, buffers,

antioxidants and/or other additives may be included, as required.

30 ¹H- and ¹³C- NMR spectra were recorded on either a Jeol GSX 270 MHZ FT-NMR spectrometer or a Brucker AMX-250 MHz NMR spectrometer operating at 20°C +/-1°C. Chemical shifts are reported in parts per million (δ) downfield from tetramethylsilane (TMS). Spin multiplicities are described as: s (singlet), bs (broad singlet), d (doublet), dd (doublet of doublets), t (triplet), q (quartet), p (pentuplet) or m (multiplet). Mass spectra (MS) were recorded using a Jeol JMS-DX 303 GC Mass Spectrometer (EI mode: 70eV,

source 117-147°C). Accurate molecular masses (HRMS) were determined by peak matching using perfluorokerosene (PFK) as an internal mass marker, and FAB mass spectra were obtained from a glycerol/thioglycerol/trifluoroacetic acid (1:1:0.1) matrix with a source temperature of 180°C. Optical rotations at the Na-D line were obtained at ambient temperature using a Perkin-Elmer 141 Polarimeter. Analytical results were generally within +/- 0.2% of the theoretical values. Flash chromatography was performed using Aldrich flash chromatography Silica Gel-60 (E. Merck, 230-400 mesh). Automated flash chromatography was carried out on a Jones Flashmaster II. Thin-layer chromatography (TLC) was performed using GF₂₅₄ silica gel (with fluorescent indicator) on glass plates. All solvents and reagents, unless otherwise stated, were supplied by the Aldrich Chemical Company Ltd. and were used as supplied without further purification. Anhydrous solvents were prepared by distillation under a dry nitrogen atmosphere in the presence of an appropriate drying agent, and were stored over 4Å molecular sieves or sodium wire. Petroleum ether refers to the fraction boiling at 40-60°C.

In vitro - clonogenic cell lines

In order to determine the activity of the compounds synthesised, solid human tumour xenografts growing subcutaneously in serial 35 passages in thymus aplastic nude mice (Naval Medical Research Institute, USA nu/nu strain) were removed under sterile condition, mechanically disaggregated and subsequently incubated

with an enzyme cocktail consisting of collagenase (41U/ml, Sigma), DNase I (125 U/ml, Roche), hyaluronidase (1000 U/ml, Sigma) and dispase II(1.0 U/ml) in RPMI 1640-Medium (Life Technologies) at 37°C for 30 minutes. Cells were passed through 5 sieves of 200 µm and 50 µm mesh size and washed twice with sterile PBS-buffer. The percentage of viable cells was determined in a Neubauer-hemocytometer using trypan blue exclusion. The cells generated were as follows:

Breast MACL MCF7
10 Renal 9442
Lung 629L
Melanoma MEXF 462NL

The clonogenic assay was performed in a 24-well format according 15 to a modified two-layer agar assay introduced by Hamburger, A.W. and Salmon, S.E., *Science*, 197, 461-643 (1977). The bottom layer consisted of 0.2 ml/well of Iscove's Modified Dulbecco's Medium (supplemented with 20% fetal calf serum and 1% gentamicin) and 0.75% agar. 4 X 10⁴ to 8 x 10⁴ cells were added to 0.2 ml of the 20 same culture medium supplemented with 0.4 % agar and plated in 24-multiwell dishes onto the bottom layer. The test compounds were applied by continuous exposure (drug overlay) in 0.2 ml culture medium. Each dish included six control wells containing the vehicle and drug treated groups in triplicate at 6 25 concentrations. Cultures were incubated at 37°C and 7.5% CO₂ in a humidified atmosphere for 8-20 days and monitored closely for colony growth using an inverted microscope. Within this period, *in vitro* tumour growth led to the formation of colonies with a diameter of >50 µm. At the time of maximum colony formation, 30 counts were performed with an automatic image analysis system (OMNICON FAS IV, Biosys GmbH). 24 hours prior to evaluation, vital colnies were stained with a sterile aqueous solution of 2-(4-iodophenyl)-3-(4-nitrophenyl)-5-phenyltetrazolium chloride (1 mg/ml, 100 µl/well).

The IC₅₀ values of the test compounds were determined by plotting compound concentration versus cell viability.

The following compounds (Cooper. N., et al., *Chem. Commun.*, **16**, 1764–1765 (2002) and WO 00/12508) were tested as comparisons:

5 NCI *In Vitro* Cytotoxicity Studies

The National Cancer Institute (NCI), Bethesda, Maryland, USA has available an *in vitro* cytotoxicity screen which consists of approximately 60 human tumour cell lines against which compounds are tested at a minimum of five concentrations each differing 10-fold. A 48 hour continuous exposure protocol is used, where cell viability or growth is estimated with an SRB protein assay.

Method

The test compounds were evaluated against approximately 60 human tumour cell lines. The NCI screening procedures were described in detail by Monks and co-workers (Monks, A *et al.*, Journal of the National Cancer Institute, 1991, 83, 757). Briefly, cell suspensions were diluted according to the particular cell type and the expected target cell density (5000-40,000 cells per well based on cell growth characteristics), and added by pipette (100 µL) into 96-well microtitre plates. The cells were allowed a preincubation period of 24 hours at 37°C for stabilisation. Dilutions at twice the intended test concentration were added at time zero in 100 µL aliquots to the wells. The test compounds were evaluated at five 10-fold dilutions (10⁻⁴, 10⁻⁵, 10⁻⁶, 10⁻⁷

and 10^{-8} μM). The test compounds were incubated for 48 hours in 5% CO_2 atmosphere and 100% humidity. The cells were then assayed using the sulphorhodamine B assay. A plate reader was used to read the optical densities and a microcomputer processed the 5 readings into GI_{50} values (in Moles), which is the dosage required to limit cell growth to 50%.

The results of these studies can be summarized by averaging log GI_{50} across all the cell lines tested to derive a MG_MID value, 10 which shows that compound 25 (MG_MID = -7.18) is more effective than compound 23 (MG_MID = -6.34).

NCI Hollow Fibre Assay for Preliminary *In Vivo* Testing

The Biological testing Branch of the Developmental Therapeutics 15 Program of the NCI has adopted a preliminary *in vivo* screening tool for assessing the potential anticancer activity of compounds identified by the large scale *in vitro* cell screen. For these assays, human tumour cells are cultivated in polyvinylidene (PVDF) hollow fibres, and a sample of each cell line is implanted 20 into each of two physiologic compartments (intraperitoneal and subcutaneaous) in mice. Each test mouse received a total of 6 fibres (3 intraperitoneally and 3 subcutaneously) representing 3 distinct cancer cell lines. These mice are treated with potential antitumour compounds at each of 2 test doses by the 25 intraperitoneal route using a QD x 4 treatment schedule. Vehicle controls consist of 6 mice receiving the compound diluent only. The fibre cultures are collected on the day following the last day of treatment. To assess anticancer effects, the viable cell mass is determined for each of the cell lines using a formazyn 30 dye (MTT) conversion assay. From this, the %T/C can be calculated using the average optical density of compound treated samples divided by the average optical density of the vehicle controls. In addition, the net increase in cell mass can be determined for each sample, as a sample of fibre cultures are 35 assessed for viable cell mass on the day of implantation into mice. Thus, the cytostatic and cytocidal capacities of the test

compound can be assessed.

Generally, each compound is tested against a minimum of 12 human cancer cell lines. This represents a total of 4 experiments since each experiment contains 3 cell lines. The data are reported as %T/C for each of the 2 compound doses against each of the cell lines with separate values calculated for the intraperitoneal and subcutaneous samples.

Compounds are selected for further *in vivo* testing in standard subcutaneous xenograft models on the basis of several hollow fibre assay criteria. These include: (1) a %T/C of 50 or less in 10 of the 48 possible test combinations (12 cell lines x 2 sites x 2 compound doses); (2) activity at a distance (intraperitoneal drug/subcutaneous culture) in a minimum of 4 of the 24 possible combinations; and/or (3) a net cell kill of 1 or more of the cell lines in either implant site. To simplify evaluation, a points system has been adopted which allows rapid evaluation of the activity of a given compound. For this, a value of 2 is assigned for each compound dose which results in a 50% or greater reduction in viable cell mass. The intraperitoneal and subcutaneous samples are scored separately so that criteria (1) and (2) can be evaluated. Compounds with a combined IP + SC score of 20, a SC score of 8 or a net cell kill of one or more cell lines are referred for xenograft testing. This comparison indicated that there was a very low probability of missing an active compound if the hollow fibre assay was used as the initial *in vivo* screening tool. In addition to these criteria, other factors (e.g. unique structure, mechanism of action) may result in referral of a compound for xenograft testing without the compound meeting these criteria.

Certain compounds of the invention were tested in variations of these assays, to assess their activity against renal and melanoma cell lines. In the melanoma assay, only 6 cell lines are used, and therefore compounds with a combined IP + SC score of 10 or a SC score of 4 are referred for xenograft testing. In the renal

assay, only three cell lines are used and therefore compounds with a combined IP + SC score of 5 or a SC score of 2 are referred for xenograft testing.

5 The results of this assay are presented below in tables 5 and 6, including results for some of the compounds disclosed in Cooper. N., et al., *Chem. Commun.*, **16**, 1764-1765 (2002) and WO 00/12508:

Table 6 - Melanoma

On the basis of these results, compounds 13 and 27 have been
15 selected to be tested in the next stage of the NCI program (xenografts) on renal cancers, whilst compounds 12 and 21 have been selected to be tested on melanomas.
